

# Overview of CaesarJ

Eduardo Figueiredo

<http://www.dcc.ufmg.br/~figueiredo>

# [ What is CaesarJ? ]

- A programming language for
  - Aspect-Oriented Programming
  - Feature-Oriented Programming
- Aims to improve software design
  - modularity, reusability, flexibility, etc.
- Fully integrated with Java
  - Compile to JVM-compatible bytecode

# [ CaesarJ Highlights ]

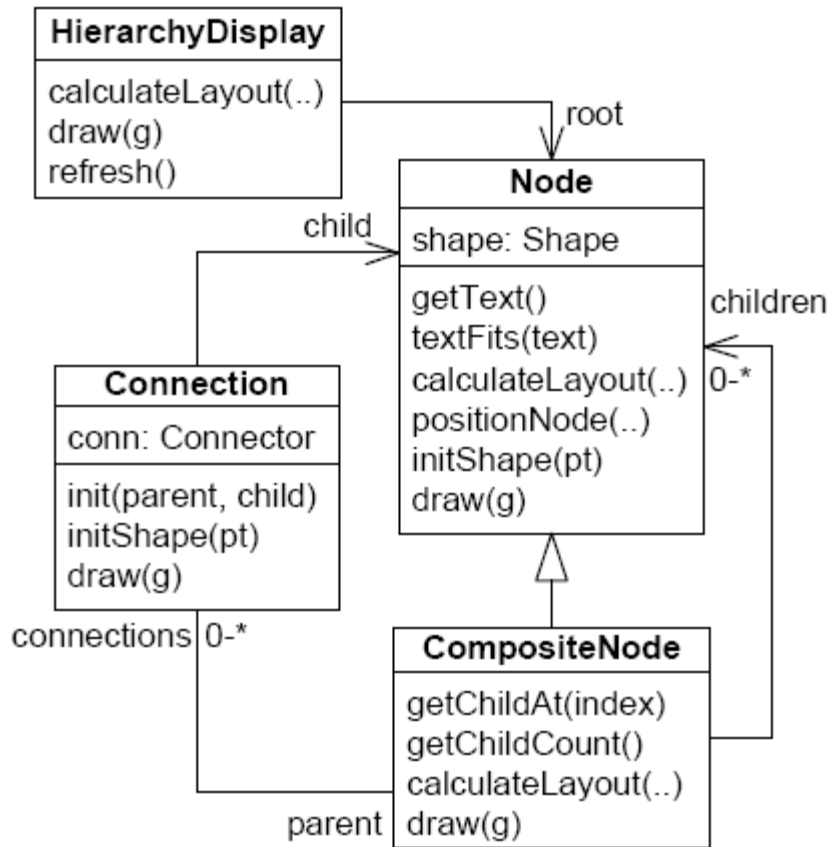

---

- Family Class
- Virtual Class
- Mixin Composition
- Binding
- Collaboration Interface
- Dynamic Deployment
- Aspectual Polymorphism

# [ Family Class ]

- Also known as CaesarJ class
  - Or *cclass*, for short
- It groups related functionality
  - Or just *classes*
- Class is a recursive definition

# [ Four Classes (OO) ]

They represent a tree

# Variability Management (SPL)

A basic tree

...with adjusted nodes

...plus angular connections

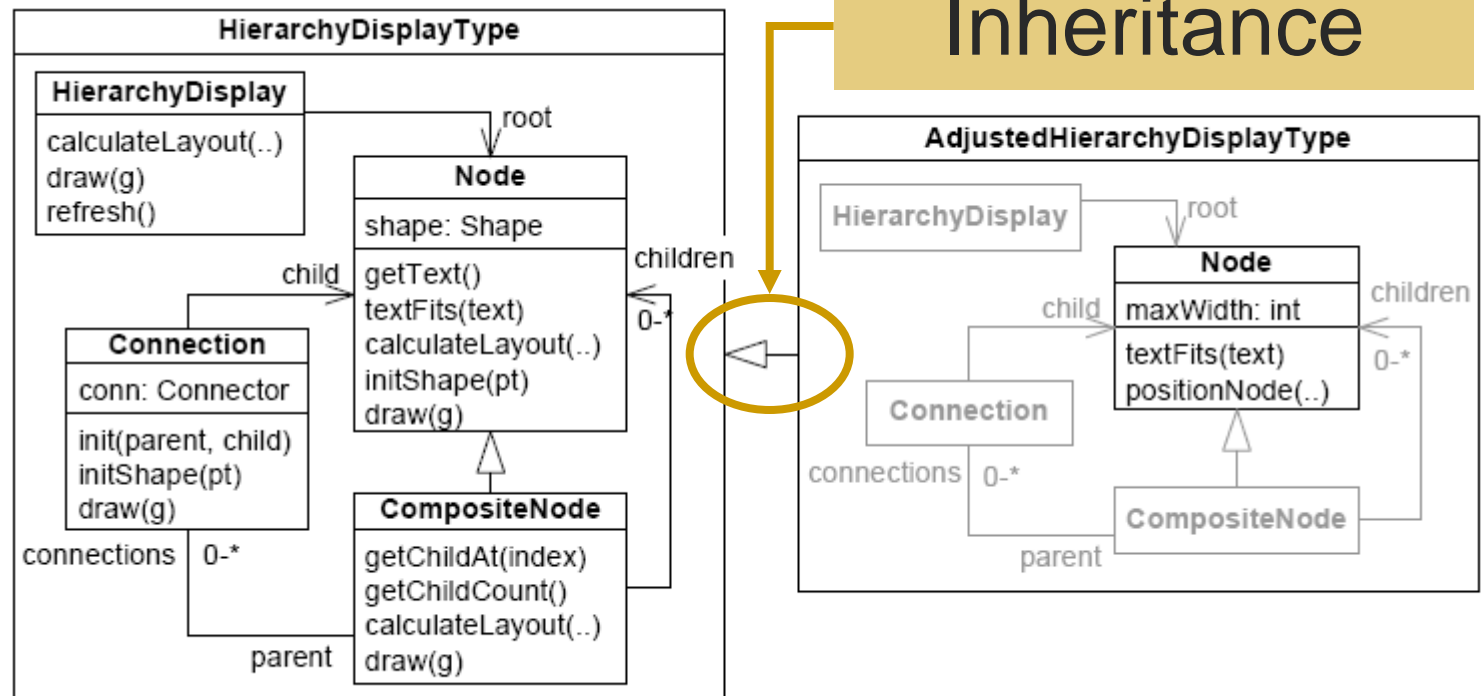

# [ Virtual Classes ]

---

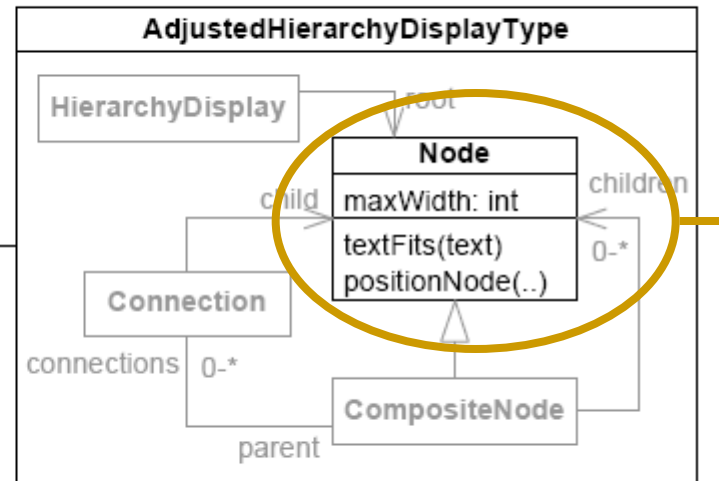

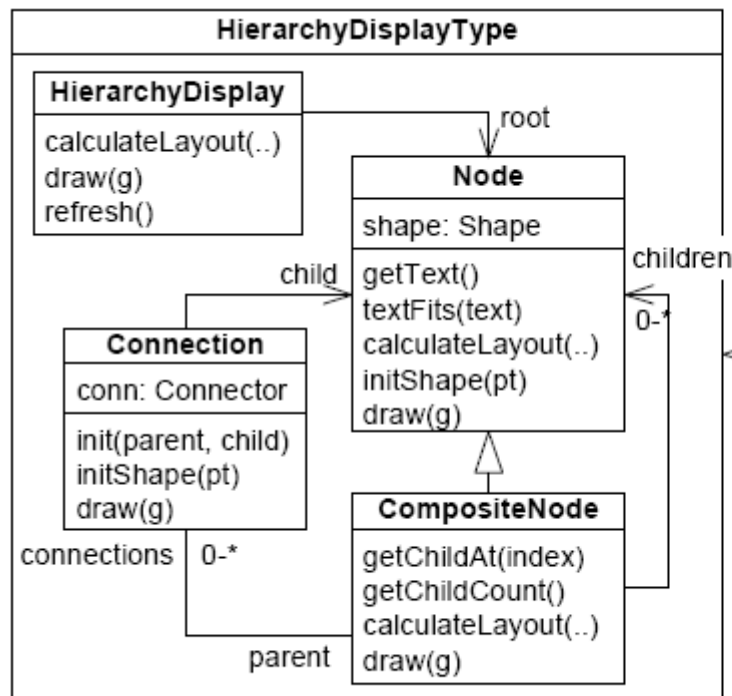

- They have different meanings depending on the dynamic context
  - Similar to virtual methods
- They are defined as inner classes of an enclosing family class (*cclass*)
  - Members of the family

# Two Family Classes

A family class is also a class

# Two Family Classes

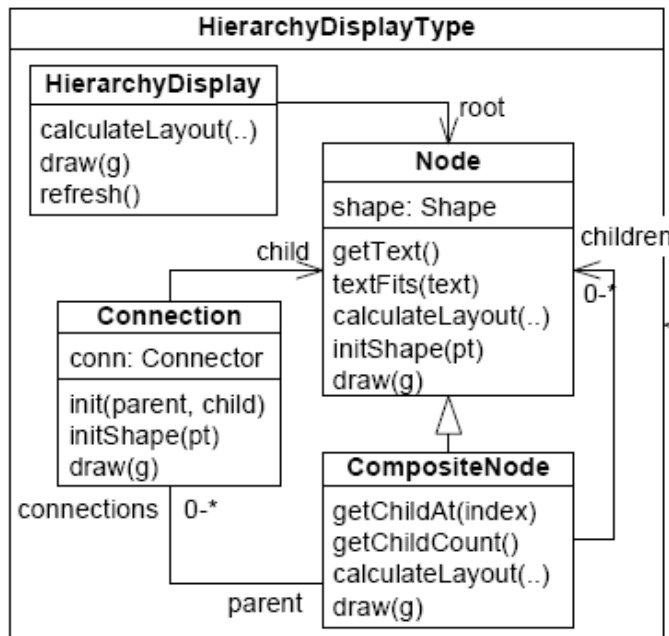

A refinement is  
a virtual class

# [Mixin Composition]

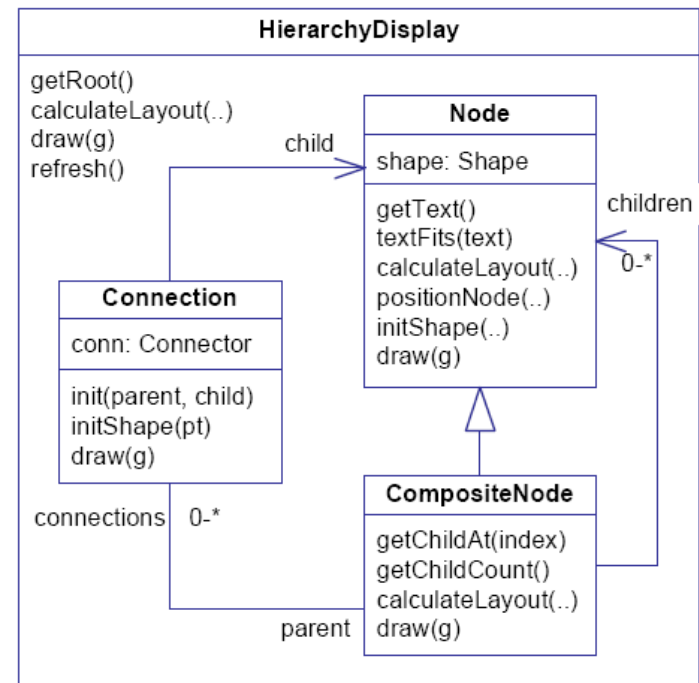

- Classes (simple or families) are mixins
  - Their superclass can be exchanged
- Mixin composition propagates into inner classes of a family class automatically
  - The display layout strategy can compose adjustable nodes with angular connections
- Unambiguousness is ensured by
  - the composition order
  - a linearization algorithm

# Members of a Family Class

- In addition to virtual classes, a family class can also have members
  - Methods, attributes, etc.

=

# HierarchyDisplay (CaesarJ)

```
cclass HierarchyDisplay {
```

```
  cclass Node { ... }
```

```
    cclass CompositeNode extends Node {
```

```
      calculateLayout() {
```

```
        Connection c = new Connection(); ...
```

```
      }
```

```
    ...
```

```
  }
```

```
  cclass Connection { ...
```

```
    void initShape(Point pt) { ... }
```

```
  }
```

```
  Node root;
```

```
  ...
```

```
}
```

Virtual Classes

Family Class

# HierarchyDisplay (CaesarJ)

```
cclass HierarchyDisplay {  
  cclass Node { ... }  
  cclass CompositeNode extends Node {  
    calculatel aayout() {  
      Connection c = new Connection(); ...  
    }  
    ...  
  }  
  
  cclass Connection { ...  
    void initShape(Point pt) { ... }  
  }  
  
  Node root;  
  ...  
}
```

Connection c = new Connection(); ...

refers to

cclass Connection { ...  
 void initShape(Point pt) { ... }  
}

Scope rules are similar to Java

# HierarchyDisplay Subclasses

```
cclass AdjustedHierarchyDisplay extends HierarchyDisplay {  
  cclass Node { ...  
    int maxwidth;  
  }  
}
```

Maxwidth is a new attribute of Node

```
void foo(Node n) { ...  
  n.maxwidth ...  
}
```

No casting is required because **n** refers to AdjustedHierarchyDisplay.Node

```
cclass AngularHierarchyDisplay extends HierarchyDisplay {  
  cclass Connection {  
    void initShape(Point pt) { ... }  
    ...  
  }  
}
```

# [ Binding ]

- CaesarJ provides two mechanisms for expressing crosscutting compositions
  - AspectJ-like pointcut/advice
  - Binding propagating mixin composition

- Example of binding

```
cclass AdjustedAngularHierarchyDisplay extends  
    AdjustedHierarchyDisplay & AngularHierarchyDisplay {}
```

# [ The & Operator ]

- A variant of multiple inheritance
  - Linearizes the superclasses avoiding ambiguities
- The operator & is not commutative
  - The left hand side is more specific
- It works recursively with arbitrary levels of nesting

# [ Collaboration Interface ]

- The interface concept is not necessary
  - CaesarJ does not have the single inheritance bottleneck
  - An abstract class cannot be instantiated
- Collaboration interface is an abstract class that controls the collaboration between different facets of its implementation

# Example: Collaboration Interface

```
abstract public class IHierarchyDisplay {
    abstract public Node getRoot();           /* data model */
    abstract public void calculateLayout();
    abstract public void draw(Graphics g);   /* visualization */
    abstract public void refresh();

    ...
    abstract public class Node {
        abstract public String getText();    /* data model */
        abstract public boolean textFits(String text); /* visualization */
    }
    abstract public class CompositeNode extends Node {
        abstract public Node getChildAt(int i); /* data model */
        abstract public int getChildCount();
        abstract public void calculateLayout(); /* visualization */
    }
}
```

# [ Dynamic Deployment ]

- Denoted by the keyword *deploy* used as a block statement
- Dynamic deployment is useful when we cannot determine which variant of a feature should be used until runtime
  - In static deployment (like in AspectJ), we have to implement all different variants by conditional logic within the aspect code

# [ Example: Dynamic Deployment ]

```
cclass Logging {  
    after(): (call(void Point.setX(int)) || call(void Point.setY(int)) ) {  
        System.out.println("Coordinates changed");  
    }  
}
```

```
cclass VerboseLogging extends Logging {  
    after(): call(void Point.setColor(Color)) {  
        System.out.println("Color changed");  
    }  
}
```

```
cclass Main {  
    public static void main(String args[]) {  
        Logging I = null;  
        Point p[] = createSamplePoints();  
        if (args[0].equals("-log")) I = new Logging();  
        if (args[0].equals("-verbose")) I = new VerboseLogging();  
        deploy (I) { modify(p); }  
    } ...  
}
```

The use of Logging  
or VerboseLogging is  
dynamic determined

# [ Example: Dynamic Deployment ]

```
cclass Logging {  
    after(): (call(void Point.setX(int)) || call(void Point.setY(int)) ) {  
        System.out.println("Coordinates changed");  
    }  
}
```

```
cclass VerboseLogging extends Logging {  
    after(): call(void Point.setColor(Color)) {  
        System.out.println("Color changed");  
    }  
}
```

```
cclass Main {  
    public static void main(String args[]) {  
        Logging I = null;  
        Point p[] = createSamplePoints();  
        if (args[0].equals("-log")) I = new Logging();  
        if (args[0].equals("-verbose")) I = new VerboseLogging();  
        deploy (I) { modify(p); }  
    } ...  
}
```

Aspectual  
Polymorphism

# CaesarJ Development Tool

# [ CJDT ]

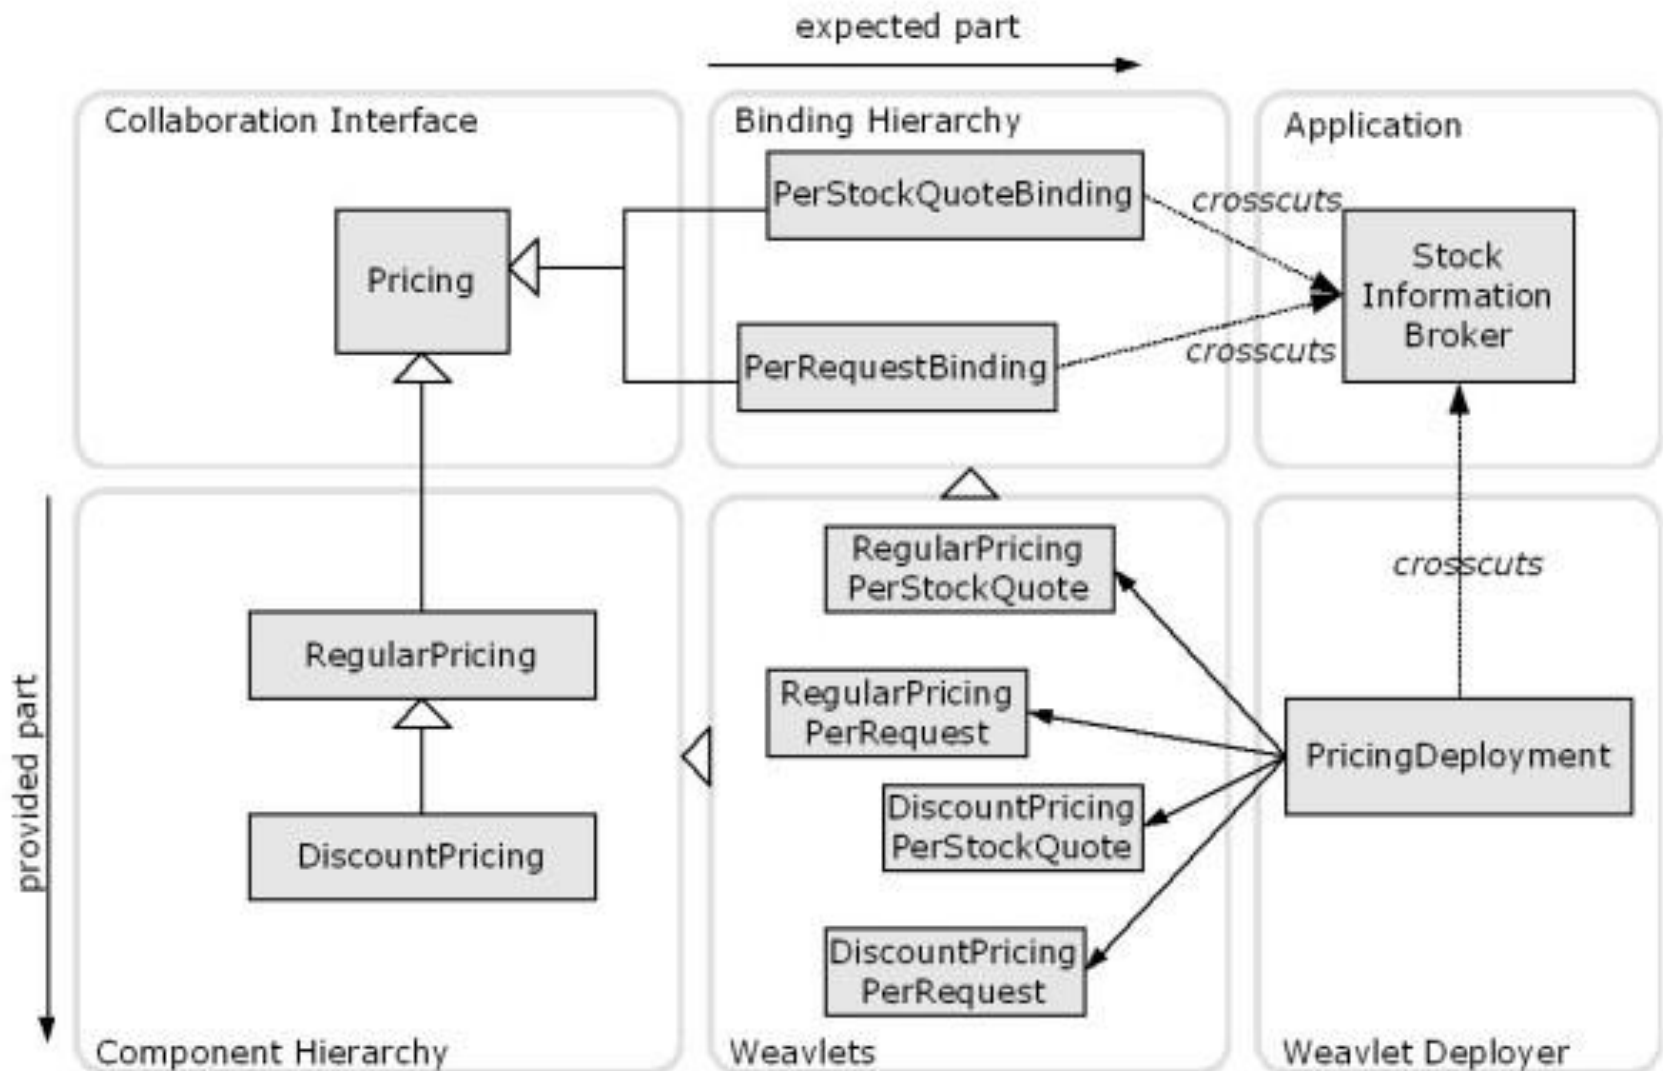

---

- Provide IDE support for the CaesarJ
  - Plug-in for Eclipse
- Eclipse extensions
  - Editor with keyword highlighting
  - Outline view
  - New project wizard
  - CaesarJ hierarchy view
  - Debugging support

# [ The Pricing Example ]

- Application for stock quotes
  - A server part
  - A client part
- The server includes a database to store information about quotes (*Hashtable*)
- The client interface provides a method to request stock quotes (*collectInfo*)

# The Pricing Example

# CaesarJ Editor

```
public deployed cclass PricingDeployment
{
    static Map pricingMapping = new HashMap();

    static
    {
        try
        {
            // User <-> Pricing Mapping
            pricingMapping.put("Klaus", new PerRequestDiscountPricing_Impl(null));
            pricingMapping.put("Egon", new PerStockQuoteDiscountPricing_Impl(null));
            pricingMapping.put("Mira", new PerRequestRegularPricing_Impl(null));
        }
        catch(Throwable t)
        {
            t.printStackTrace();
        }
    }

    void around(Client c) :
        (execution(void Client.run(String [])) && this(c))
    {
        deploy (pricingMapping.get(c.getName()))
    }
}
```

Deployed cclass weave crosscutting code

# Debugging Support

The screenshot displays the Eclipse IDE interface during a debug session. The title bar reads "Debug - MAIN.java - Eclipse Platform". The menu bar includes File, Edit, Navigate, Search, Project, Run, Window, and Help. The toolbar contains icons for file operations and debugging actions like Run, Breakpoint, and Step Over.

The Debug Console shows the following structure:

- MAIN [Java Application]
  - myPackage.MAIN at localhost:6340
    - Thread [main] (Suspended (breakpoint at line 6 in MAIN))
      - MAIN.main(String[]) line: 6
  - C:\j2sdk1.4.2\_05\bin\javaw.exe (19.10.2004 20:22:02)

HelloWorld.java World.java MAIN.java PricingDeployment.java

```
package myPackage;

public class MAIN {
    public static void main(String[] args) {
        HelloWorld test = new HelloWorld();
        test.sayHelloTest("Hello World");
    }
}
```
